Is there any standard way to do this? A: There is the Advanced Web Server for Android, which implements some of the methods described in XMLHttpRequest (see the WebContentClient interface), like FileReader.load and FileReader.readAsBinaryString. Another approach, if you don't need to work with binary data, would be to send the bytes of the file in an HTTP request. This should be done through the REST API of your Android application. JSON format is not supported in ISO-8859-1: using PHP header I am trying to make a request to the route /api/v1/branches which returns a list of all branches in the database, using $client->request('GET','/api/v1/branches'); Which is working great, however the JSON response is being returned to me as ISO-8859-1 (something like that, but not exactly) and I cannot do the normal JSON decoding. Is there any way to specify that the response must be JSON or how can I convert this response to be a JSON response. The problem is that I was sending the request from a phone, so the default header that is being sent from Android is UTF-8, but PHP is sending the response as ISO-8859-1. So I had to set header('Content-Type: application/json'); in my PHP code 82157476af
